
(a-c) P1's correlation cache: one measurement per event pair, station and phase; P on the vertical component, S on both horizontals combined (non-negative, hence no negative S). (d) libhdd's own double-difference files; residuals beyond ±300 ms are off the axis (cross-correlation 4.4% first / 3.0% last; catalog 8.1% / 8.1%). In the last iteration 95% of the positive correlations (P and S) and 81% of the negative ones (all P) still carry weight. (e) Open symbols: first iteration; filled: last; 'correlation data' = the double differences measured by cross-correlation. (f) P1pos moves the events by a median of 38 m relative to P1 (74 events by more than 100 m).
