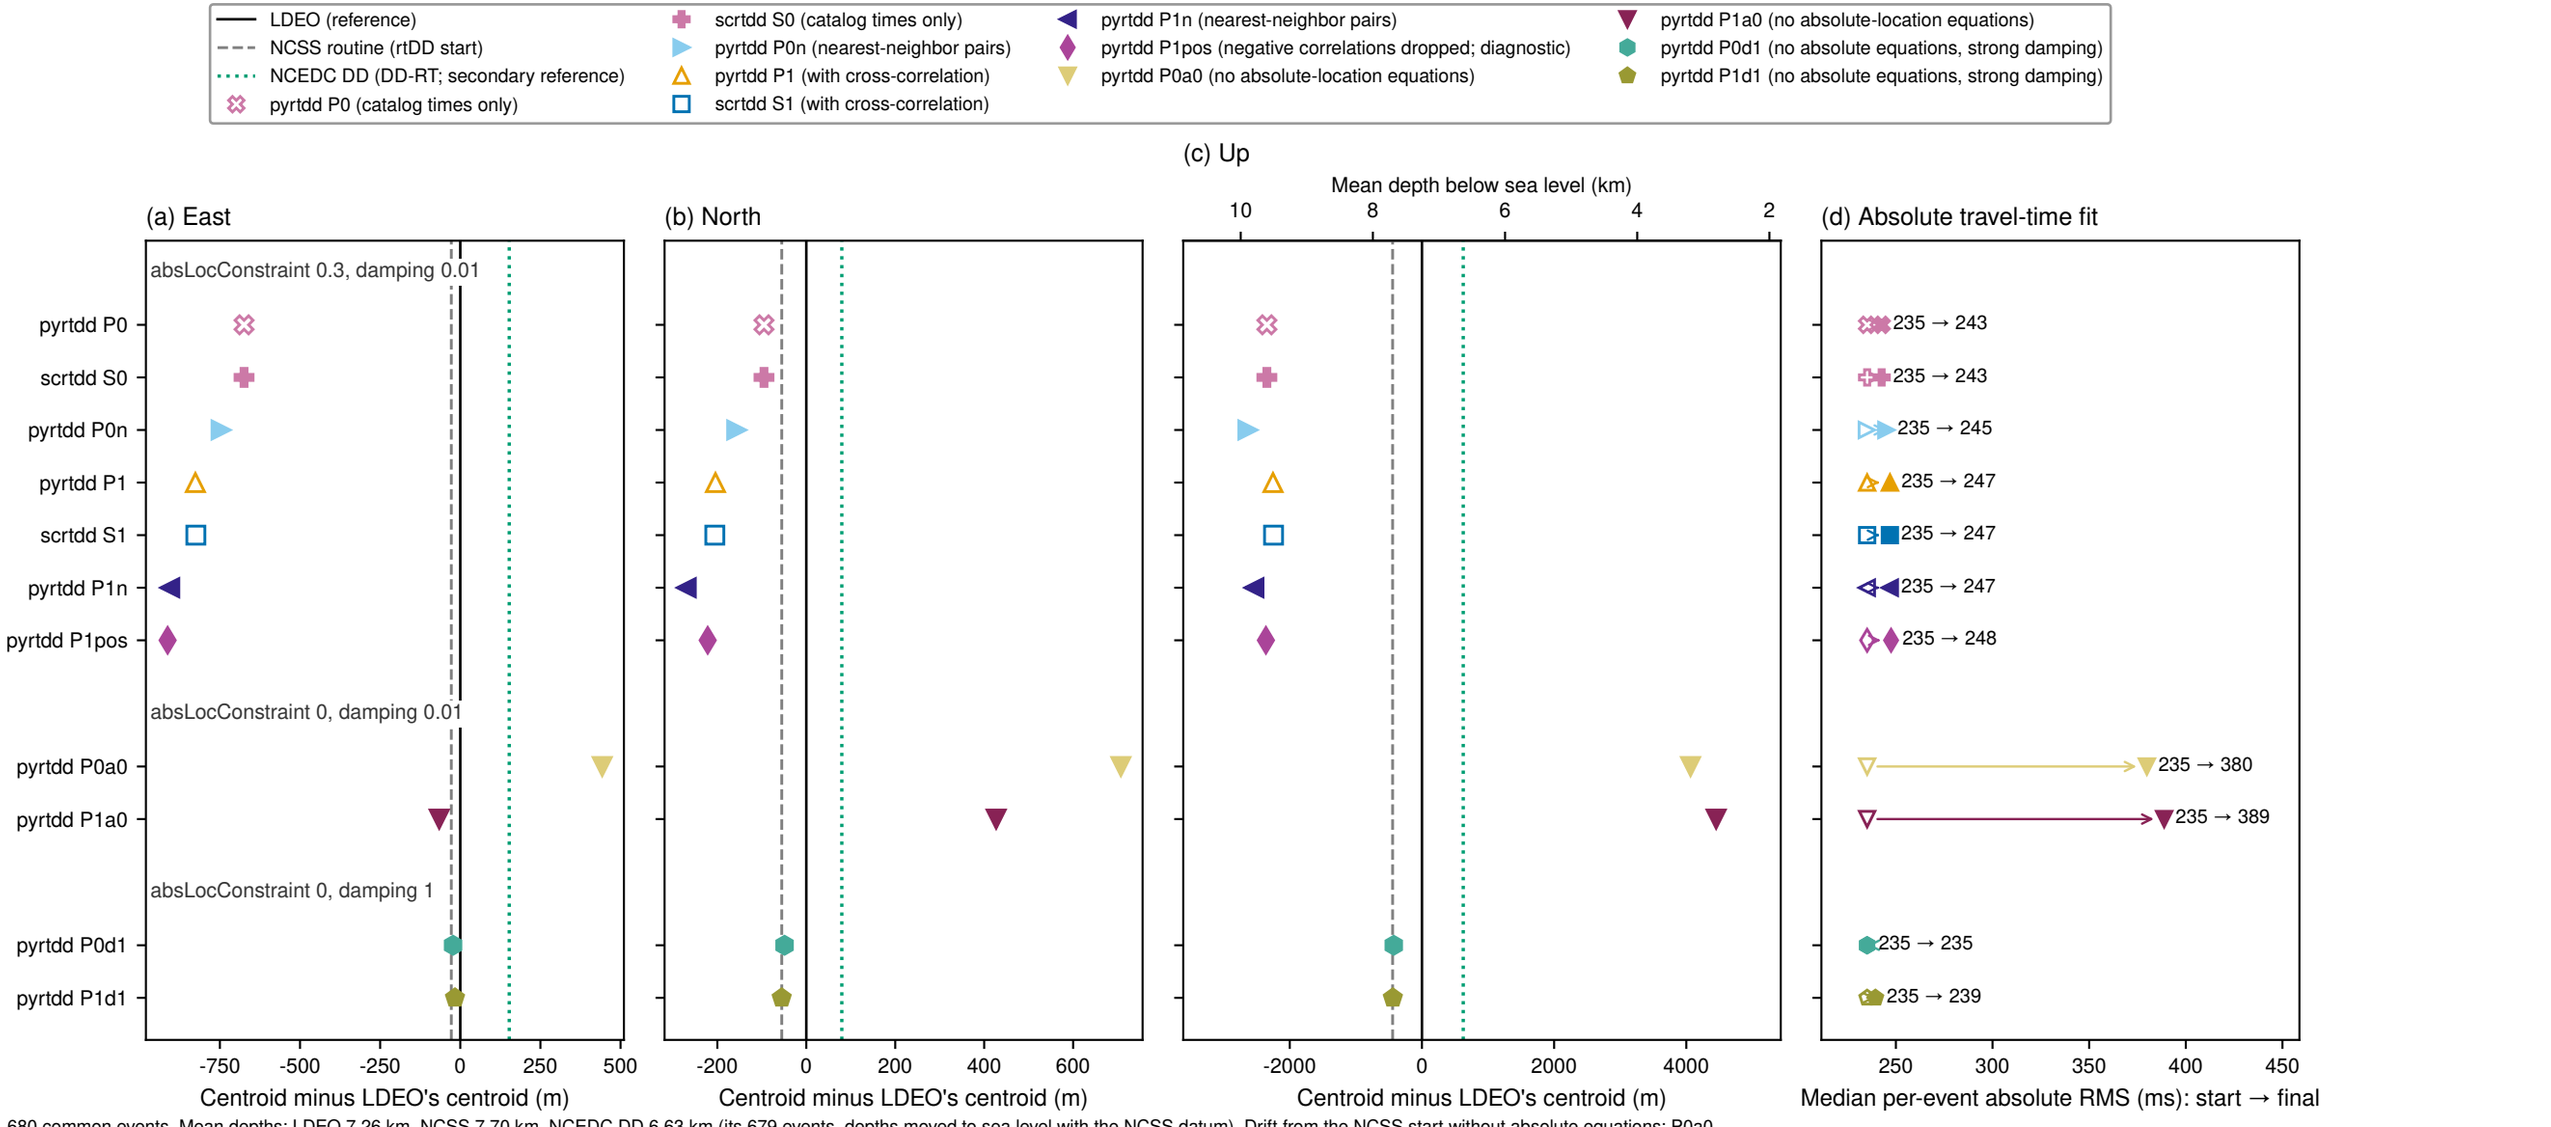
Do not use the absolute positions: the default solver puts the swarm 2.2-2.6 km deeper than LDEO, without absolute equations it ends 4.1-4.5 km shallower, and strong damping keeps it at the NCSS start (427-440 m deeper than LDEO)



680 common events. Mean depths: LDEO 7.26 km, NCSS 7.70 km, NCEDC DD 6.63 km (its 679 events, depths moved to sea level with the NCSS datum). Drift from the NCSS start without absolute equations: P0a0 4.5 km up, P1a0 4.9 km up. (d) rtDD's startRms / finalRms per event (CON model, no station corrections).
